Abstract—In the Big Data era, the visualization of large data sets is becoming an increasingly relevant task due to the great impact that data have from a human perspective. Since visualization is the closer phase to the users within the data life cycles phases, there is no doubt that an effective, efficient and impressive representation of the analyzed data may result as important as the analytic process itself. Starting from previous experiences in importing, querying and visualizing WordNet database within Neo4J and Cytoscape, this work aims at improving the WordNet Graph visualization by exploiting the features and concepts behind tag clouds. The objective of this study is twofold: first, we argue that the proposed visualization style is able to put order in the messy and dense structure of nodes and edges of WordNet, showing as much as possible information from the lexical database and in a clearer way; secondly, we think that the tag cloud approach applied to the synonyms rings reinforces the human cognition in recognizing the different usages of words in a language like English. The ultimate goal of this work is, on the one hand, to facilitate the comprehension of WordNet itself and, on the other hand, to investigate techniques and approaches to get more insights from the visual representation and analytics of large graph databases.

Keywords—WordNet; Big Data; Data and Information Visualization; Neo4J; Graph Database; NoSQL.

I. INTRODUCTION

A subtle difference exists between *data* and *information*. The first is raw, it simply exists and has no significance beyond its existence (in and of itself) [1]. Data are just numbers, bits of information, which ‘...have no way of speaking for themselves. We speak for them. We imbue them with meaning.’ [2]. On the contrary, information is data that has been given meaning by way of relational connection, by providing context for them. Even more subtle is the distinction between *Data Visualization* and *Information Visualization*. If the main goal of the first one is to communicate information clearly and efficiently to users, involving the creation and study of the visual representation of data – i.e., “information that has been abstracted in some schematic form, including attributes or variables for the units of information” [3] – the main task of the second one is the study of (interactive) visual representations of abstract data to reinforce human cognition. The abstract data may include both numerical and non-numerical data, such as text and geographic information. Beyond Information Visualization, an other outgrowth field is *Visual Analytics* that can be defined as ‘the science of analytical reasoning facilitated by interactive visual interfaces.’ [4]. Today, in many spheres

of human activity, massive sets of data are collected and stored. As the volumes of data available to various stakeholders such as business people or scientists increase, their effective use becomes more challenging. Keeping up to date with the flood of data, using standard tools for data management and analysis, is fraught with difficulty. The field of visual analytics seeks to provide people with better and more effective ways to understand and analyse these large datasets, while also enabling them to act upon their findings immediately, in real-time [5]. Thus, the challenges that the Big Data imperative [6][7] imposes to data management severely impact on data visualization. The “bigness” of large data sets and their complexity in term of heterogeneity contribute to complicate the representation of data, making the drawing algorithms quite complex. Just to make an example, let us consider the popular social network Facebook, in which the nodes represent people and the links represent interpersonal connections; we note that nodes may be accompanied by information such as age, gender, and identity, and links may also have different types, such as colleague relationships, classmate relationships, and family relationships. The effective representation of all the information at the same time is really challenging. The most common solution is to use visual cues, such as color, shape, or transparency to encode different attributes. In this regard, tag clouds are a popular method for representing variables of interest (such as popularity, frequency of occurrence of a term, and so on) in the visual appearance of the keywords themselves using text properties such as font size, weight, or color [8]. Since the study conducted in this paper consists in the visual representation of WordNet as a large graph in Neo4j [9] and Cytoscape [10], a particular attention is paid to *Graph Visualization*, referring to other well-known works in the literature for a complete review of the techniques and theories in Information Visualization [11][12].

Graphs are traditional and powerful tools for visually representing sets of data and the relations among them by drawing a dot or circle for every vertex, and an arc between two vertices if they are connected by an edge. If the graph is directed, the direction is indicated by drawing an arrow. The pioneering work of W. T. Tutte [13] was very influential in the subject of graph drawing, in particular he introduced the use of linear algebraic methods to obtain graph drawings. Basically, there are generally accepted aesthetic rules to draw a graph [14], which include: distribute nodes and edges evenly, avoid edge crossing, display isomorphic substructures in the same

manner, minimize the bends along the edges. However, since it is quite impossible to meet all rules at the same time, some of them conflict with each other or they are very computationally expensive, practical graphical layouts are usually the results of compromise among the aesthetics. There exists different graph visualization layouts in literature, such as: the Tree Layout, the Space Division Layout, the Matrix Layout and the Spring Layout[15], to mention a few. The latter will be used in this work and it is worth to spending few words on it. Spring layout, also known as *Force-Directed* layout, is a popular strategy for general graph visualization. The strategy consists in modeling the graph as physical systems of rings or springs. The attractive idea about spring layout is that the physical analogy can be very naturally extended to include additional aesthetic information by adjusting the forces between nodes. As one of the first few practical algorithms for drawing general graphs, spring layout is proposed by Eades in 1984 [16]. Since then, his method is revisited and improved in different ways [17]. Mathematically, Spring layout is based on a cost (energy) function, which maps different layouts of the same graph to different non-negative numbers. Through approaching the minimum energy, the layout results reaches better and better aesthetically pleasing results. The main differences between different spring approaches are in the choice of energy functions and the methods for their minimization. Specifically concerning the visualization of WordNet, there are not many works in the literature. In [18], the authors make an attempt to visualize the WordNet structure from the vantage point of a particular word in the database, this in order to overcome the down-side of the large coverage of WordNet, i.e., the difficulty to get a good overview of particular parts of the lexical database. An attempt to apply design paradigms to generate visualizations which maximize the usability and utility of WordNet is made in [19], whereas, in [20] a radial, space-filling layout of hyponymy (IS-A relation) is presented with interactive techniques of zoom, filter, and details-on-demand for the task of document visualization, exploiting the WordNet lexical database. The visualization approach used in this work uses the Spring layout to draw the graph-based representation of WordNet in Cytoscape and a tag cloud-based strategy to represent the synonym rings from WordNet. Moreover, as a general rule the principled representation methodology we agree on is the *Visual Information Seeking Mantra* presented by Scheiderman in [21]. It can be summarized as follows: “overview first, zoom and filter, then details-on-demand”.

The reminder of the paper is organized as follows. Section II describes the WordNet meta-model, while Section III, after a clarification of ground concepts related to WordNet landscape, describes how WordNet has been imported in Neo4J and its visualization in Cytoscape. Section IV goes to the hearth of this work *rationale* by illustrating the way a tags cloud approach is used to effectively draw the graph of WordNet synonyms rings in Cytoscape. Finally, Section V draws the conclusion summarizing the major findings and outlining future investigations.

II. WORDNET CASE STUDY

The case study presented in this paper consists in the *reification* of the WordNet database inside the Neo4J GraphDB. WordNet [22][23] is a large lexical database of English. Nouns, verbs, adjectives and adverbs are grouped into sets

of cognitive synonyms (synsets), each expressing a distinct concept. Synsets are interlinked by means of conceptual-semantic and lexical relations. In this context, we have defined and implemented a meta-model for the WordNet reification using a conceptualization as much as possible close to the way in which the concepts are organized and expressed in human language [24]. We consider concepts and words as nodes in Neo4J, whereas semantic, linguistic and semantic-linguistic relations become Neo4J links between nodes. For example, the hyponymy property can relate two concept nodes (nouns to nouns or verbs to verbs); on the other hand a semantic property links concept nodes to concepts and a syntactic one relates word nodes to word nodes. Concept and word nodes are considered with *DatatypeProperties*, which relate individuals with a predefined data type. Each word is related to the represented concept by the ObjectProperty *hasConcept* while a concept is related to words that represent it using the ObjectProperty *hasWord*. These are the only properties able to relate words with concepts and vice versa; all the other properties relate words to words and concepts to concepts. Concepts, words and properties are arranged in a class hierarchy, resulting from the syntactic category for concepts and words and from the semantic or lexical type for the properties. The subclasses have been derived from the related categories. There are some union classes useful to define properties domain and codomain. We define some attributes for Concept and Word respectively: Concept *hasName* that represents the concept name; *Description* that gives a short description of concept. On the other hand Word has Name as attribute that is the word name. All elements have an ID within the WordNet offset number or a user defined ID. The semantic and lexical properties are arranged in a hierarchy. in Table I some of the considered properties and their domain and range of definition are shown.

TABLE I. PROPERTIES

Property	Domain	Range
hasWord	Concept	Word
hasConcept	Word	Concept
hyponym	NounsAnd VerbsConcept	NounsAnd VerbsConcept
holonym	NounConcept	NounConcept
entailment	VerbWord	VerbWord
similar	AdjectiveConcept	AdjectiveConcept

The use of domain and codomain reduces the property range application. For example, the hyponymy property is defined on the sets of nouns and verbs; if it is applied on the set of nouns, it has the set of nouns as range, otherwise, if it is applied to the set of verbs, it has the set of verbs as range. in Table II there are some of defined constraints and we specify on which classes they have been applied w.r.t. the considered properties; the table shows the matching range too.

Sometimes the existence of a property between two or more individuals entails the existence of other properties. For example, being the concept dog a hyponym of animal, we can assert that animal is a hypernymy of dog. We represent this characteristics in OWL, by means of property features shown in Table III.

TABLE II. MODEL CONSTRAINTS

Constraint	Class	Property	Constraint range
AllValuesFrom	NounConcept	hyponym	NounConcept
AllValuesFrom	AdjectiveConcept	attribute	NounConcept
AllValuesFrom	NounWord	synonym	NounWord
AllValuesFrom	AdverbWord	synonym	AdverbWord
AllValuesFrom	VerbWord	also_see	VerbWord

TABLE III. PROPERTY FEATURES

Property	Features
hasWord	<i>inverse</i> of hasConcept
hasConcept	<i>inverse</i> of hasWord
hyponym	<i>inverse</i> of hypernym; <i>transitivity</i>
hypernym	<i>inverse</i> of hyponym; <i>transitivity</i>
cause	<i>transitivity</i>
verbGroup	<i>symmetry</i> and <i>transitivity</i>

III. IMPORTING WORDNET IN NEO4J AND VISUALIZING IT IN CYTOSCAPE

The WordNet lexical database has been imported in Neo4J [25] and afterward visualized in Cytoscape according to a procedure similar to that described in a previous work by the authors [26]. In a nutshell, the procedure consists in accessing the WordNet files through the JWI (Java Wordnet Interface) APIs [27][28], collecting all the information about *synsets*, *words* and *word senses* in four different csv files, and finally, loading all the csv lines in Neo4J through the Neo4J *LOAD CSV* macro. Compared to the previous one, this work focuses on the visualization of WordNet and the most expensive part of the work has consisted in defining a Cytoscape custom style to represent the *synonyms rings* as tag clouds in an effective and clear way. This surely represents the novelty of this approach. We preferred to load WordNet objects from JWI APIs and serialize them in custom csv files, which were then imported throughout Cypher macros, instead of using already existing WordNet RDF serialization [29], because, this way, we could add some useful information in the csv lines like the *word frequency*, the *polysemy*, and so forth, for the sake of the successive representation in Cytoscape. And that is also why we prefer to create a custom tool to import the WordNet database in Neo4J instead of using already existing tools. Before diving into the procedure details, it is worth to clarify the distinction and provide some useful definitions coming from JWI APIs about *synsets*, *synsets (or synonyms) rings*, *index words* and *word senses*. Figure 1 try to put light on this. As discussed in the previous section, a synset is a concept, i.e., an entity of the real world (both physical or abstract) meaning something whose meaning can be argued by reading the *gloss* definition provided by WordNet. Its meaning can be also understood by analysing the semantic relations linking it to other synsets or by the synset (or synonyms) ring. This one is a set of words (hereafter mentioned as index words) generally used in a specific language (such as English) to refer to that concept. The term synset itself is used to refer to set of synonyms meaning a specific concept. On the contrary, an index word is just a term, i.e., a *sign* without meaning; so that, only when we link it to a specific concept we obtain a word sense, i.e., a word provided with a meaning. An index word has got different meanings according to the context in which it is used and because of a general characteristic of

languages: the *polysemy*. For example, the term *home* has nine different meanings if it is used as noun, and so, it belongs to nine different synsets. In fact, the WordNet answer when we search for *home* is the following:

- (430) home, place — (where you live at a particular time; "deliver the package to my home"; "he doesn't have a home to go to"; "your place or mine?")
- (350) dwelling, home, domicile, abode, habitation, dwelling house — (housing that someone is living in; "he built a modest dwelling near the pond"; "they raise money to provide homes for the homeless")
- (116) home — (the country or state or city where you live; "Canadian tariffs enabled United States lumber companies to raise prices at home"; "his home is New Jersey")
- (43) home — (an environment offering affection and security; "home is where the heart is"; "he grew up in a good Christian home"; "there's no place like home")
- (38) home, nursing home, rest home — (an institution where people are cared for; "a home for the elderly")
- (36) base, home — (the place where you are stationed and from which missions start and end)
- (7) family, household, house, home, menage — (a social unit living together; "he moved his family to Virginia"; "It was a good Christian household"; "I waited until the whole house was asleep"; "the teacher asked how many people made up his home")
- (7) home plate, home base, home, plate — ((baseball) base consisting of a rubber slab where the batter stands; it must be touched by a base runner in order to score; "he ruled that the runner failed to touch home")
- (3) home — (place where something began and flourished; "the United States is the home of basketball")

Figure 1. WordNet synsets, index words and word senses.

In addition to synsets glosses, WordNet gives us some useful statistic information about the usage of the term *home* in each synset. The position of the term in each synonyms ring tell us how usual is the use of the term to signify that concept. The position of the term in each synset is a measure of the usage frequency of the term for each concept: higher the position, higher the frequency. Moreover, by counting the number of synsets which a term belongs to, it is possible to obtain its polysemy (e.g., the number of possible meanings of *home*). JWI is able to tell us all this information about synset and word senses. In particular, for each synset we have collected the following fields in the csv files:

- 1) *Id*: the univoque identifier for the synset;
- 2) *SID*: the Synset ID as reported in the WordNet database;
- 3) *POS*: the synset's part of speech (POS);
- 4) *Gloss*: the synset's gloss which express its meaning;
- 5) *Level*: the hierarchical level of synset in the whole WordNet hierarchy.

For word senses we have collected the following fields:

- 1) *Id*: the univoque identifier for the word sense;
- 2) *POS*: the word's part of speech (POS);
- 3) *polysemy*: the word polysemy;
- 4) *frequency*: the word frequency of the word sense as previously explicated.

A third csv file stores the semantic links existing between synset by reporting the IDs of the source and target synset

and the type of semantic link existing between them, such as hypernym, hyponym, meronym, etc.

In addition to the previous files, a final file lists the links between each word sense and each synset. This file is very simple, it just contains a line for each pair (Word Sense, Synset) in WordNet. Other minor and not significant fields have been added for the sake of the visualization in Cytoscape, such as *label* (a human readable label for the nodes) and *dimension* (used to suggest a plausible diameter for the Synset node representation according to its depth in the WordNet hierarchy). The code to convert WordNet synsets into csv tables is available at <https://github.com/eureko/WordNetToCSVFiles/>.

In order to import all the information contained in the csv files and translate them into a graph data structure inside Neo4J [9], the meta-model described in Section II has been used. Each synset and word sense have been converted into a node of the graph with label respectively: *Synset* and *WordSense*. Each semantic relation has become an edge between two synset nodes with the *type* property expressing the specific semantic relation holding between the concepts. Finally, the word sense nodes have been connected to their related concepts nodes through a specific relation. This allows to effectively represent synonyms ring through the Neo4J web visualizer. For example, Figure 2 shows the results of the following Cypher query:

```
match (a: WordSense {POS: 'NOUN'})-[r]->(c: Synset)
      where (c)-[l]-(: WordSense {label: 'home'})
      return a,r,c
```

The figure reports nine synset rings for the term *home*. The filled circles represents the synset and contain the synset gloss definition, while the white circles around contain the word terms used to signify such synset.

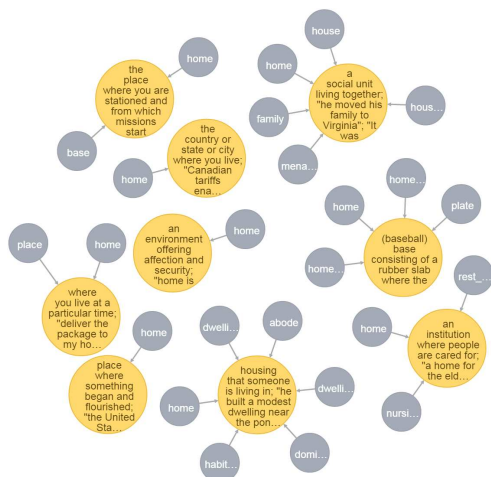

Figure 2. WordNet synset rings containing the 'home' word

IV. THE TAG CLOUD-BASED REPRESENTATION OF WORDNET SYNONYMS RINGS

The work described in this paper has encountered challenges that are quite close to the typical Big Data scenario. In fact, this version of WordNet graph (v. 2.1) includes 117597 synsets rings containing 207106 word senses conveyed by 155327 index words, 283837 semantic relations (cfr., Section II) linking synsets each other and 207016 semantic-lexical links between index words and synsets. With these big numbers,

Figure 3. Large scale representation of 5000 relations and 3404 synsets in WordNet

the manipulation, the querying and the visualization of the graph become quite challenging. The visualization of the entire structure of WordNet in terms of all synsets, words, semantic and lexical relations in a way that is elegant and intelligible at the same time, is a *chimera*, due to the performance issues of the visualization tools, in particular when sophisticated drawing algorithms are used, and to the strongly connected nature of information to be represented, which often results in a messy and dense structure of nodes and edges. Just to have an idea, Figure 3 shows a representation of an excerpt of WordNet (5000 semantic relations over 3404 synsets) obtained from *Cytoscape v.3* graph visualization tool. The Neo4j running instance has been accessed via a specific plug-in, namely *cyNeo4j*, that converts the query results into Cytoscape table format and then create a view according to a custom style and a selected layout like the *Force-directed graph drawing algorithm* before mentioned. The resulting figure is more considerable for global analysis, or for its look and feel, than for actual information that you can retrieve from it. Nevertheless, thanks to the force-directed algorithm, it is possible to observe agglomerates of nodes and edges which correspond to specific semantic categories and can help users in zooming the desired semantic area.

Thus, it is necessary to simplify the representation of the network by following some functional and esthetic criteria. In this regard, we have selected some simple representation criteria, listed as follows:

- 1) the efficiency of the visualization, i.e., avoid the information redundancy and the proliferation of useless signs and graphics as much as possible;
- 2) the effectiveness of the visualization, i.e., grant that the graphical representation of the network covers the whole informative content of the WordNet graph-based implementation;
- 3) the clearness of visualization, i.e., use light colors, such as gray, light blue, dark green, etc. with a proper level of brightness and with an appreciable contrast.

is large in size and as a strong gray shade because of its low polysemy (1) and high frequency when used in the context of baseball.

Figures 5(a) and 5(b) show more representations of WordNet excerpts to fully demonstrating the customized style resulting from this work. The figure are obtained through the following Cypher query where 'keyword' is substituted with *book* and *time*:

```
MATCH (a: WordSense {label: '<keyword>'})-[r]->
      (b: Synset)-[t: semantic_property]->
      (f: Synset)-[s]-[c: WordSense]
      return a,r,b,t,f,s,c
```

The figures above also highlights the semantic relations existing between synsets showing a more complete representation of WordNet with the new visualization style described in this work.

V. CONCLUSION AND FUTURE WORK

Starting from previous experiences in importing, querying and visualizing WordNet in Neo4J and Cytoscape, a tag cloud based approach has been proposed in this paper as a new solution to make more effective and intelligible the representation of the WordNet graph. The results shown in this work are twofold: first, the new visualization style is able to put order in the messy and dense structure of nodes and edges of WordNet, showing as much as possible information from the lexical database and in a clearer way; secondly, the tag cloud approach is able to reinforce the human cognition in recognizing the different usages of words in English, w.r.t. the concepts they are related to. In fact, the proposed solution not only shows the synsets and the semantic relations holding between them, but also gives clues about the frequency of use of the synonyms for each synset. Future investigation may surely go in the direction of improving the criteria to simplify the WordNet representation with an evaluation for the visualization methods also validated by usability tests in which the user can express a consensus whether the representation is friendly or not, and the information inside WordNet is easily accessible or not. Finally, according to other studies, which aim at improving the tag cloud with semantics [30] and adding multimedia information to the knowledge representation model [31], we will investigate on the use of semantic properties and more efficient metrics to measure the relatedness among WordNet terms, also applying other visual features to combine these information and improve the quality of WordNet visualization.
